Advisory

Advisory: Vendor Window patch comparison.

Two gateway vendors proposed different weekends for a signing change.

Findings: Northwind Gateway 4.2 rejects telemetry that fails signature checks, which created a two-hour monitoring gap in the March rehearsal.

Sable Route 7.1 queues unsigned telemetry for review instead of dropping it, at the cost of a larger holding directory.

Recommended posture: Prefer a queue-during-change posture and verify the trust store before the weekend window..

Assessment

Assessment method: Each vendor configuration was rehearsed once on a lab gateway with the same unsigned-sample stream.

Observed outcome: Northwind produced a two-hour visibility gap while Sable retained the samples and used 18 GB of extra disk.

Boundaries: Neither rehearsal measured analyst time spent clearing the queue or rebuilding the gap.

Unresolved items: Can the two products be run in parallel for one cycle without double-counting alerts?
Exposure: Severity high: Dropping unsigned telemetry without a queue can hide a collector outage during the change window.

Recommended action: Confirm the trust store and keep a temporary queue before the Saturday change..
