Summary

Memorandum on Patch Desk change-window brief.

Leadership asked for a single page before the weekend signing change.

Patch Desk recommends a temporary review queue rather than a hard drop during the first change window.

The brief limits its recommendation to the lab rehearsal evidence and the duty-officer ladder.

Operator decision: Enter the weekend window with a temporary queue, a confirmed trust store, and an explicit rollback trigger..

Evidence

Method note: The brief used the lab rehearsal outcome and the severity ladder, and did not add production estimates.

Reported result: The recommended posture was queue-during-change, with rollback if the holding directory grows without a stated cap.

Limits of the evidence: No production traffic sample was available, so load during the window is unknown.

Open questions: What queue depth would force a rollback during the window? Risk review: Severity high: A hard drop during the first window can open a monitoring gap if signatures fail closed.

Recommended action: Keep the temporary queue and define a rollback if the queue depth grows without bound..
